

ABSTRACT

Developing a personal assistant is the main goal of the research, especially for Windows-based operating systems. AI voice assistant is an idea inspired by real- life virtual assistants such as her Cortana and Siri for their respective Windows and iOS platforms that perform various tasks from the command line and create a user-friendly interface.

This software is a synchronous process that uses and analyses human-dependent artificial language as the basis for speech recognition and processing. It can perform various tasks and serve end-users according to their requirements. The purpose of most of the wizards developed was to customize automation to perform a variety of specific tasks, from sending emails to managing tasks. With the development of technology that has dramatically increased human dependence on computers, people and users want their devices to be simpler and more convenient, and even text-to-speech in providing commands and input. There was a transition. This change marked the beginning of speech recognition. This has created a need to not only get input by voice, but also perform tasks and commands via speech recognition. This was the idea behind the personal voice assistant.
